# Background

### Automata theory

#### Finite automata

- Processes input symbol by symbol with finite memory
- The finite memory indicates whether the word as seen so far satisfies the condition to be checked.

# Check multiple of 3

#### Automatic relations

- Encode idea of process tuples in parallel
- ullet Add a padding symbol #
- $conv(010, 01236) = \binom{0}{0}\binom{1}{1}\binom{0}{2}\binom{\#}{3}\binom{\#}{6}$
- A function is automatic iff its graph (encoded this way) is automatic

## Verifying addition

#### Primary school algorithm

- n correct and no carry
- c − carry
- i wrong

## Correct addition

2 3 5 8

# 1 1 2

2 4 7 0

nnncn

#### Incorrect addition

3 3 3 3

# # 2 2

# 1 5 5

iinnn

#### Automatic structures

A structure  $(A,f_1,\ldots,f_n,R_1,\ldots,R_m)$  is automatic iff

- A is a regular set,
- $f_1, \dots, f_n$  are automatic functions,
- $R_1, \dots, R_m$  are automatic relations.

### Example

 $(\mathbb{N},+)$  is automatic but  $(\mathbb{N},+,\cdot)$  is not automatic.

### Semiautomatic structures

$$(A,f_1,\ldots,f_n,R_1,\ldots,R_m;g_1,\ldots,g_p,S_1,\ldots,S_q)$$
 is semiautomatic iff

- A is a regular set,
- $f_1,\ldots,f_n$  are automatic functions and  $R_1,\ldots,R_m$  are automatic relations,
- $g_1,\ldots,g_n$  are semiautomatic functions and  $S_1,\ldots,S_m$  are semiautomatic relations,

where  $f:A^n\to A$  is semiautomatic iff fixing n-1 inputs, the resultant  $A\to A$  function is automatic.

### Semiautomatic structures

### Example

 $(\mathbb{N},+,<,=;\cdot)$  is not automatic.

For any constant n, implement multiplication by n as repeated addition.

### Set theory

### **Ordinals**

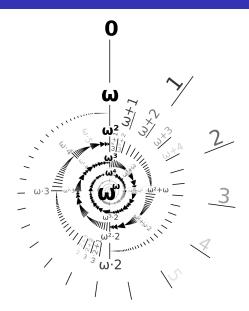

Equivalence classes of well-order, where a well-order (S,<) obeys trichotomy, transitivity and well-foundedness (every nonempty subset has a minimum).

Intuitively, measures how many times a discrete process is repeated (possibly transfinitely many). For example,

$$\begin{array}{l} 0,1,2,3,\ldots,\omega,\omega+1,\ldots,\omega+\omega=\omega\cdot 2,\\ \omega\cdot 2+1,\omega\cdot 2+2,\ldots,\omega\cdot 2+\omega=\omega\cdot 3,\ldots,\omega\cdot 4,\ldots,\\ \omega\cdot \omega=\omega^2,\ldots,\omega^3,\ldots,\omega^\omega,\ldots. \end{array}$$

One way to generalise sum and products to infinite structures.

### **Ordinals**

### Semiautomatic Ordinal Structures

## **Existing characterisation**

### Theorem (Delhommé)

For any ordinal  $\alpha$  the structure  $(\alpha, +, <)$  is automatic iff  $\alpha < \omega^{\omega}$ .

#### **Proof Sketch**

Consider  $\alpha=\omega^n$  , any  $\beta\in\alpha$  is of the form

$$\omega^{n-1} \cdot c_{n-1} + \dots + \omega \cdot c_1 + c_0$$

for coefficients  $c_0,\dots,c_{n-1}\in\mathbb{N}.$ 

We can define + on the n-ary convolution of an automatic copy of  $(\mathbb{N},+,<)$ .

## Incorporating semiautomaticity

**Observation.** Using the same representation, when  $\beta \in \alpha$  is fixed, we can define left and right-multiplication by  $\beta$  in an automatic manner. (Addition and multiplication on ordinals are not commutative)

#### Theorem

For any ordinal  $\alpha<\omega^\omega$  the structure  $(\alpha,+,<,=;\cdot)$  is semiautomatic.

## Left multiplication

Let

$$\begin{split} \beta &= \omega^k \cdot b_k + \omega^{k-1} \cdot b_{k-1} + \dots + \omega \cdot b_1 + b_0 \\ \gamma &= \omega^l \cdot c_l + \omega^{l-1} \cdot c_{l-1} + \dots + \omega \cdot c_1 + c_0 \end{split}$$

expanding the giant expression, we get

$$\begin{split} \beta \cdot \gamma &= \beta \cdot \omega^l \cdot c_l + \beta \cdot \omega^{l-1} \cdot c_{l-1} + \dots + \beta \cdot \omega \cdot c_1 + \beta \cdot c_0 \\ \dots \\ &= \omega^{k+l} \cdot c_l + \omega^{k+l-1} \cdot c_{l-1} + \dots + \omega^{k+1} \cdot c_1 \\ &+ \left(\omega^k \cdot (b_k \cdot c_0) + \omega^{k-1} \cdot b_{k-1} + \dots + \omega^{b_1} + b_0\right) \cdot 1_{c_0 \neq 0} \end{split}$$

where  $1_{c_0\neq 0}$  is 1 is  $c_0\neq 0$  and 0 otherwise.

## Right multiplication

Ordinal multiplication distributes on the right, so we get a finite composition of

- right-multiplication by  $\omega$ ,
- right-multiplication by fixed constants,
- ordinal addition.

## Right multiplication by $\omega$

$$\begin{split} \left(\omega^3 \cdot b_3 + \omega^2 \cdot b_2 + \omega \cdot b_1 + b_0\right) \cdot \omega \\ &= \begin{cases} \omega^4 & \text{if } b_3 > 0 \\ \omega^3 & \text{if } b_3 = 0, b_2 > 0 \\ \omega^2 & \text{if } b_3 = 0, b_2 = 0, b_1 > 0 \\ \omega & \text{if } b_3 = 0, b_2 = 0, b_1 = 0, b_0 > 0 \\ 0 & \text{otherwise} \end{cases} \end{split}$$

### Semiautomatic ordinals at $\omega^\omega$ and beyond

### Overview

### Theorems (Jain, Khoussainov, Stephan, Teng and Zou)

- Let  $\alpha$  be any countable ordinal, the structure  $(\omega^{\alpha};+,<,=)$  is semiautomatic.
- The semiring of polynomials over  $\mathbb{N}$   $(\mathbb{N}[x];+,\cdot,=)$  is semiautomatic.

## Polynomials over N

- Fix an semiautomatic copy A of  $(\mathbb{N},+,<;\cdot)$ , add new "connectives"  $\oplus,\otimes$
- ullet Represent polynomials as lists of coefficients from A
- Represent elements as polynomials with connectives between them
  - $1,10,2\oplus 0,4$  represents the expression  $(2x^2+10x+1)\cdot (4x)$
- ullet Define the quotient map val sending an expression to the canonical representation.
- val is not automatic, but for any polynomial  $p \in \mathbb{N}[x]$ , there is an automatic fragment of val that is "good enough".

## Polynomials over $\omega$

- We need even more connectives  $\oplus_l, \oplus_r, \otimes_l, \otimes_r$
- For arbitrarily large  $k \in \mathbb{N}$ ,  $k + \omega = \omega$  and  $\omega \cdot k \cdot \omega = \omega \cdot \omega$
- Refine error conditions to deal with this

#### Conclusion

The structure  $(\omega^{\omega}; +, <, \cdot, =)$  is semiautomatic.

# Semiautomatic Ring Structures

### Overview

Rings are obtained by adding to an Abelian group a notion of multiplication.

Theorem (Jain, Khoussainov, Stephan, Teng and Zou)

For any  $n \in \mathbb{N}$  the ring  $(\mathbb{Z}(\sqrt{n}), \mathbb{Z}, +, <, =; \cdot)$  is semiautomatic.

## Illustrating square roots

We illustrate with the simplest case, let  $u=\frac{1+\sqrt{5}}{2}$  denote the golden ratio.

Theorem (Jain, Khoussainov, Stephan, Teng and Zou)

 $(\mathbb{Z}[u], +, <, =; \cdot)$  is semiautomatic.

## The ingredients

ullet  $3=u^{-2}+u^2$  for any  $x+yu\in\mathbb{Z}[u]$ , so update coefficients until

$$x + yu = \sum_{i} a_i u^i$$

but now each  $|a_i| \leq 2$ .

• Tail bound –  $\sum_{i\leq 2}u^i$  is a geometric series

## Sign test

- To check if a + b = c we perform sign test on a + b c.
- Given a list of coefficients, we slide over them and use the equation  $u^2=u+1$  to update our memory
- $\bullet$  The first time any coefficient overshoot  $4\cdot \sum_{i\leq 2} u^i$  , by our earlier tail bound we will know the sign
- If all input is processed, do a finite case distinction
- Use the characterisation that automatic functions are also computable by linear-time one-tape Turing machines where input and output start at the same position (Case, Jain, Seah and Stephan) to look through coefficients in order.

### Generalising to cube roots

# The case of $\sqrt[3]{7}$

Let  $u^{-1}=2-\sqrt[3]{7}$  and we use a similar strategy to show  $(\mathbb{Z}[u],+,<,=;\cdot)$  is semiautomatic.

To achieve our coefficient bound we have

$$u^3 - 12u^2 + 6u - 1 = 0$$

where 12 dominates.

 The tail bound is also geometric, but since we update two coefficients at once in every step of the sign test, we need more refined bounds.

# The case of $\sqrt[3]{7}$

- $\bullet$  Denote our current coefficients  $a_i,a_{i+1},a_{i+2}$  and we terminate if any condition here is broken
  - $|a_{i+2}| \le 16k'$ ,
  - $\bullet \ |a_{i+1}| \leq 4k' \text{, or}$
  - $|a_i| \leq k'$ , or

where k' = 360.

This gives us a semiautomatic ring containing  $\sqrt[3]{7}$ .

### Conclusion

### Contributions

- Incorporate notion of semiautomaticity into small ordinals (below  $\omega^{\omega}$ ).
- Found semiautomatic rings containing cube roots, generalising existing result.

#### Future directions

On ordinals

### Question

For how large  $\alpha$  can we find semiautomatic representations of  $(\alpha;+,<,\cdot,=)$ ?

### Future directions

On semiautomatic rings

#### Question

For every algebraic number c is there a semiautomatic ring with order which contains c?

#### Question

Is there a semiautomatic ring with order that simultaneously contains  $\sqrt{2},\sqrt{3}$  and  $\frac{1}{2}?$ 

When these  $\tilde{3}$  numbers are simultaneously present, the ring has enough information to encode the angle 15 degrees.
